

THE STORY

The Place Where Counting Fails

The story of a question about seven stars

NARRATIVE

KEITH SHIRLEY

The Place Where Counting Fails

The Story of a Question About Seven Stars

Narrative Edition

Keith Shirley

22 November 2026

One: The paragraph that would not close

It began with a paragraph that was supposed to be the end of something.

I had been working on a long thesis about human variation, nine parts of it, asking in each part what is actually shared between people and what only looks shared. Near the end there is a breath that deals with symbols, and it asks a simple question that turns out to be very hard: is there any symbol anywhere on Earth that people hold in common because they inherited it, rather than because they each arrived at it separately?

Almost everything fails that test. Circles, spirals, crosses, sun-discs, zigzags for water. They turn up everywhere, and they turn up everywhere because a circle is easy to draw and the sun is round. Shared form is not shared descent.

But there was one candidate that would not go away, and it was not a shape. It was a group of stars.

Across five continents, in languages with nothing in common, people call a particular small cluster in the winter sky **seven**. And almost everybody who looks at it sees **six**.

And in a great many of those places, people have a story about the missing one.

That was the paragraph. I graded the question contested, which is what you do when you have found something you cannot resolve, and I moved on.

I did not move on.

Because a pattern that recurs can always be explained by convergence. People all over the world invented pottery; nobody thinks they inherited it from one potter. But a pattern that recurs **carrying the same defect** is a different kind of thing altogether. If a story is simply useful, every culture will tell its own version and the versions will not share an error. If every version carries the same error, something was passed along.

So the question was whether the missing sister is a shared error.

What follows is what happened when I went and looked. It took two books and a third, and nineteen separate investigations, and four hundred and fifty-three sources, and it ends in a place I did not expect: not in the sky at all, but about four inches behind your eyes, at a boundary that was measured in a psychology laboratory in 1949 by a man who had never heard of any of this.

Two: The most storied thing in the sky

Go outside on a clear winter evening and find Orion. Follow the three stars of his belt up and to the right, past a bright orange star, and keep going. You will come to a small misty knot that looks, at first, like a smudge on your glasses.

That is the Pleiades, and it is the most storied object in the history of human looking.

Three things about it do nearly all the work in this story, and it is worth having them before anything else.

It sits almost on the ecliptic, within about four degrees of the line the sun walks through the year. So the sun crosses it annually, the moon occults it monthly, and its comings and goings are locked to the seasons.

It is tiny. The whole cluster fits inside two degrees of sky, which is four full moons laid side by side. Its members are far nearer to each other than to anything else, so when it rises out of the dawn or vanishes into the sunset it does so all at once, sharply, on a particular morning you could mark.

And nothing in it is in charge. Its brightest star is magnitude 2.9: easy to see, nowhere near dominant. Compare its neighbour the Hyades, which has the blazing orange Aldebaran sitting in it. The Pleiades has no leader. It is a committee.

Remember those three. They come back at the end as the explanation for everything, and then they get corrected, and the correction is the best part.

Three: The claim

In 2020 two astronomers, Ray Norris and his son Barnaby, published a proposal that is serious, carefully argued, and has since become the popular account of this cluster.

They noticed the two puzzles together. Why do the stories resemble each other so strongly across cultures that could not have met, typically seven young women pursued by a man associated with Orion? And why does everybody say seven when everybody sees six?

Their answer is elegant. **The stars themselves have moved.** The Pleiades are a real physical cluster drifting through space, and their members are not static relative to one another. Run the proper motions backwards about a hundred thousand years and two of them, Pleione and Atlas, which now sit too close together for an unaided eye to split, were far enough apart to be seen as two.

So on their reading, once there really were seven. People counted seven, told a story about seven, and then over tens of thousands of years the stars closed up and the count went wrong, and the story stayed. The missing sister is not a myth. She is a memory, and she is the oldest surviving story on Earth.

They point out, reasonably, that the Greek and Aboriginal Australian versions share specific elements rather than merely resembling each other, and that the two traditions cannot have borrowed.

And the reference books back the premise. Stith Thompson, the great cataloguer of folk motifs, wrote that the constellation is nearly always imagined as a group of seven sisters whose myths explain why only six are visible. That one sentence, repeated through a century of encyclopaedias, is most of the reason the idea feels like established fact rather than a hypothesis.

It is a beautiful proposal. I wanted it to be true.

Four: Thirteen peoples

The only way to test it was to go and look at the actual traditions, one at a time, in their own words, and to refuse from the start to treat "the Pleiades story" as one thing.

So I broke it into four separate elements and counted them independently for every people. Is the cluster **a group of women**? Is there **a pursuit**? Is **one of them missing and explained**? And does it **run the calendar**?

Then thirteen peoples, in an order where each one was chosen to be the hardest available test of whatever the ones before had established.

Greece first, because it is the lens every other tradition has been read through. The daughters of Atlas, pursued by Orion, and three separate explanations for the missing one: Merope ashamed of marrying a mortal, Electra hiding her face from the burning of Troy, and a seventh taken by a god. All four elements present, elaborated, and written down.

Then Aboriginal Australia, the strongest independent parallel in the world, which cannot have come from Greece. The Seven Sisters songlines run for thousands of kilometres. Women pursued by a man. The resemblance is real and it is the single best piece of evidence the proposal has.

But Australia also gave the first crack. The Torres Strait holds Tagai, and there the cluster is **six**, and they are **men**, and nobody is missing. Arnhem Land has the women as the partners of the men rather than the pursued. One continent, and the motif was already coming apart.

South Asia solved the same arithmetic problem a completely different way. The Krittika are six, explicitly, and the seventh is not lost at all: she is Arundhati, relocated to a different part of the sky, a faithful wife pointed out at weddings. A missing star turned into a moral institution.

The Eurasian steppe and southern Siberia reversed the whole thing. The Turkic name is *Ülker*, which carries the sense of an army of scattered detachments, a battle formation before it is any kind of tale. And where there is a story it runs backwards: seven men, and a girl who is stolen.

The eastern woodlands of North America flipped the gender entirely. The Cherokee have the *Ani'tsutsă*, the Boys, seven of them, and the one who fell became a pine tree. The Haudenosaunee have seven boys and a falling star. Not sisters. Brothers.

Mesopotamia was the hinge, and it is where the proposal started to die.

Here is a civilisation with five thousand years of continuous astronomical records, a leap-year algorithm triggered by this very cluster, a lunar-station system that puts it first, a cult, an iconography, and a legal symbol. The Pleiades are the **Sebettu**: seven gods, and they are **male**, and there is **no story about a missing one**. Not a trace. For two thousand years of writing.

That is the first absence in the whole investigation that actually means something, and it forced me to make a rule I used ever afterwards. **An absence in a vast record means something. An absence in a fragmentary record means nothing.** Mesopotamia wrote everything down. If they had a lost Pleiad we would know.

China was the second literate astronomy, and it agreed. *Mao*, the Hairy Head, the eighteenth lunar mansion, the mane of the White Tiger of the West. Thousands of years of records. No sisters. No pursuit. Nobody missing.

Bantu Africa gave something different and very useful: a tradition whose spread can actually be traced. Across dozens of languages the cluster is *isiLimela*, *kilimia*, and variants, and the root means **to dig, to hoe, to cultivate**. The Digging Stars. Not seven of anything. Not women. A farming instruction, spread with farming, visible in the vocabulary of forty languages like a dye in water.

Then the controlled comparison, and it is the best thing in the first book. The Khoikhoi, the Nama and the San have shared one patch of southern African sky for centuries. Their languages are related; their stories about this cluster are not. The San tell of a hopeless hunter and his angry wife. The Khoikhoi have their own version, with the pursuit **inverted**. The stories differ completely.

And the names agree. *!Khunuseti*, to gather together. A crowded bunch of small stars.

One sky, two peoples, different stories, same name. That tells you, as nothing else can, which layer is older.

The Amazigh held both readings at once, daughters of the night and simply "the group." **Mesoamerica and the Andes** had no sisters at all: the rattlesnake's rattle for the Maya, *Tianquiztli*, the marketplace, for the Aztec, and *Qullqa*, the storehouse, in the Andes.

And Māori last, where the count itself breaks. Matariki is **nine** in the restored tradition, and the missing member is not lost but **recovered**: knowledge that was interrupted and then deliberately brought back, written up, taught, and finally made a public holiday in 2022.

Five: What was actually there

Thirteen peoples. Four elements. Here is what the map came out as.

The sisters are a minority. Thompson's sentence, the one in every encyclopaedia, holds for two of twelve peoples. Four traditions make the cluster explicitly male. Many more make it neither.

The pursuit is rarer still. Four traditions in the full form, and in several others it is inverted, displaced or absent.

And the calendar column is full. Thirteen for thirteen. Every single people in the study uses this cluster to tell the time, and they do it whether the stars are sisters, brothers, gods, a tiger's mane, a digging stick, a marketplace or a granary.

That is the first finding, and it is not the one I went looking for.

The reason is geometric. The cluster sits within four degrees of the ecliptic and is compact enough that six different annual events are sharp: the dawn rising, the dawn setting, the evening rising, the evening setting, the culmination, and the disappearance. Somewhere in the world, each one of those six is somebody's new year.

Nobody was taught this. An object with those coordinates will be made into a calendar by anyone who stays outdoors long enough.

And wherever the layers can be dated or compared, **the use is older than the tale**. The Greek name probably meant the sailing stars before anybody was anybody's sister. Krittika heads the oldest Vedic lists because it rose due east at the equinox, and the seven wives arrive later. The Turkic name is a battle formation first. Mesopotamia and China have five thousand years of calendar work between them and no story at all. And in southern Africa two unrelated peoples share a name and differ on everything else.

The function came first. The story is the wrapping.

Six: Nobody got the seven by counting

Then the correlation that ends the argument, and it is complete, with no exception anywhere.

Where a tradition committed to a number larger than the eye reliably delivers, it generated an explanation for the shortfall. Eight explanations, in six traditions, no two alike, and several of them explaining physically different things. A woman ashamed. A woman veiled for a burning city. A boy who became a pine tree. A star relocated and made into a wedding rite. A girl stolen by seven men.

Where no number was committed, nothing is missing and nothing is explained, however rich the story. The Digging Stars are not seven. The marketplace is not seven. The Rain Stars are not seven. Nothing is absent from any of them.

So the missing sister is not an inherited wound. It is **a local arithmetic problem, created wherever a culture brought a number to the sky, and solved locally, every time**.

Which raises the real question. If the eye does not supply the seven, where does it come from?

It came from somewhere else, every time, and the somewhere else is different in each case. Mesopotamia brought it from a number system in which seven was already structural. The Cherokee brought it from their own sacred number. The Eurasian steppe brought it across from the seven of the Great Bear, which genuinely is seven and genuinely can be counted. And English brought it from Greece.

The number seven has never been part of this cluster's name in any language except modern English. Not in Sumerian, not in Akkadian, not in Arabic, not in Sanskrit, not in Chinese, not in Japanese, not in Nahuatl, not in Māori, not in any Bantu or Khoe-San language reached.

We are the odd ones. We named it for a count we cannot see, and then wondered why it did not add up.

Seven: A word in Japanese

Here is where the story turns, and it turns because of somebody else.

In the first sweep there was a short section on Japan, and in it one line that I had written down as a curiosity and not thought about. The Japanese name for the Pleiades is **Subaru**, and it means **gathered together**.

A third voice in the room, reading the draft, picked that line out and said it was the heart of the thing.

It was.

Because once you are looking for it, it is everywhere, and it is the layer underneath all the stories.

Kimah, a heap, in Hebrew, Aramaic and Syriac. *Kupa* and *Hramadka*, a heap and a little crowd, in Belarusian. *al-Thurayya* in Arabic, read as a herd of camels. MUL.MUL in Sumerian, simply the Stars. *Tagemmunt*, the group, in Amazigh. *!Khunuseti*, to gather together, in Khoikhoi. A crowded bunch of small stars in the Kalahari. *Ülker*, an army of scattered detachments, on the Turkic steppe. *Tianquiztli*, the marketplace, in Nahuatl. *Te Huihui o Matariki*, the assembly, in Māori. And *Subaru*, gathered together, in Japanese.

Fourteen traditions. At least nine unrelated language families. Six continents and across the Pacific.

Not one of them is a story. Every one of them is a description.

And it explains why this layer is the one that spread furthest, while the sisters did not. A story needs a teller, an occasion and an authority, and all three can be interrupted. A **name** is carried by children learning to talk. It is the cheapest thing in any culture to transmit and the hardest to stop.

Which is why the first book ends where it does. The sisters are not humanity's oldest story. But underneath them is something older and stranger: that everybody who ever walked outside and looked at that particular patch of sky saw the same thing first, before any number and before any name for a sister or a god.

They saw that there were many of something, together, in one place.

I thought that was the end.

Eight: The problem with being right

It was not the end, because of a flaw I could see and could not fix.

I had explained the gathering-names by three properties of the object. The cluster is **plural**, several things. It is **compact**, close together. And it is **leaderless**, with nothing in charge. A thing that is several, close together, with nothing dominating it, is a crowd, and no culture has to be taught that.

The trouble is that I had read those three properties **off the Pleiades** and then offered them as the reason for the Pleiades. The argument had no exit. It could not be wrong about anything, which is another way of saying it had not yet said anything.

An account built backwards from one case will fit that case perfectly, and fitting is not evidence.

So the first book ended with a question rather than a conclusion. **What do the other clusters get called?** If gathering-names track those three properties, the explanation becomes predictive. If the Hyades, which has a leader, is called a crowd as often as the Pleiades is, the explanation is dead.

To answer that properly I had to do something uncomfortable. I had to **write down the predictions before looking**, date them, fix them, and include a definition of what would count as a gathering-name, so that an inconvenient result could not later be quietly reclassified.

That file exists and has not been edited. Everything in the second half of this story rests on it having been written first.

Nine: The correction that arrived before the first search

And then, before a single new source was opened, the whole thing had to be rebuilt, by an object nobody had thought to ask.

Orion's Belt.

It is plural: three stars. It is compact: about three degrees, comparable to the Pleiades at two. And it is leaderless to a degree nothing else in the sky approaches. Alnilam at 1.69, Alnitak at 1.74, Mintaka at 2.23. A range of about half a magnitude.

The Pleiades spans four times that. Orion's Belt is the most leaderless object in the entire study.

By my own rule it should be the heap of heaps.

It is never a heap. Not in any language on Earth.

It is three pigs among the Sotho and the Tswana, and three dogs chase them. It is three male tortoises hung on a stick among the /Xam. It is three zebras among the Nyae Nyae, one male flanked by two females. It is three travellers, three widows, three stars in a row, three kings, three Marys, three brothers, three canoe paddlers, three dancing young men, three vertebrae, three golden grains, a yardstick, an ell, a scale, a line, an arrow with three joints, and among the Seri of northwestern Mexico it is a mule deer, a pronghorn and a bighorn sheep, named individually.

Every single one of them counts it.

So the rule was wrong as stated, and the missing term is not subtle. A fourth property had to be added, and it turns out to be the one that matters:

> Gathering-names attach to what is plural, compact, leaderless **and past the point where counting is easy**.

Three is countable. Six or seven blurred together is not.

Which reframes the whole finding, and the new version is better:

A heap-name is not a description of a crowd. It is what a language reaches for when counting has already failed.

That went into the sealed file, and then I went to test it against six objects, each one chosen to break exactly one property, in an order where the first was the one most likely to destroy the hypothesis.

Ten: The Bear that could have ended it

Ursa Major first, deliberately, because it is the most dangerous object in the sky for this argument.

It is plural, seven stars. It is leaderless, with nothing brighter than 1.76 and nothing fainter than 3.3, which is about as even as a bright figure gets. And it has more recorded names in more unrelated traditions than anything except the sun and the moon.

If people simply call groups of stars crowds, this is where the evidence would be overwhelming.

It is a wagon in Germany, Charles's Wain in older English, Karlavagnen across Scandinavia, Odin's wagon in the Norse reading, a long chariot on the Assyrian tablets. A plough in Britain, a dipper in America, a saucepan in France, a ladle in Malaysia, a bushel with a handle in China. A bier in the Arabic reading, with three daughters walking behind it, a funeral still printed in the official star catalogues as Benetnasch. A bear in Greece and across much of Native North America. A camel, a shark, a skunk, a sickle. Seven plough-oxen in Rome, whose name *Septentrio* became the ordinary Latin word for north. The Seven Sages in India. The Seven Gods in Mongolia. The Drinking Gourd in the songs of the Underground Railroad.

Not one gathering-name. Anywhere.

Every name is a shape, or a count, or both. And it gave two findings I had not gone looking for.

The first: nobody is ever missing. Seven stars, seven oxen, seven sages, seven gods, counted correctly across thousands of years and dozens of traditions, and not one of them has a lost member, a hidden one, or a story explaining an absence.

Set that beside the Pleiades with its eight explanations in six traditions. Same species. Same kind of object. The difference is not history or importance. **It is twenty-three degrees of angular separation.**

A missing star is not something the sky contains. It is a residue left behind when a number meets an object that cannot supply it, and Ursa Major supplies its number, so nothing is left behind.

The second: it is not a calendar anywhere. It cannot be. Above about forty degrees north it never sets, so it never returns, and a calendar needs a return. So everybody made it a **compass** instead. The Odyssey steers by it. The Underground Railroad walked by it. The Chinese made it the Northern Dipper, the handle swinging round the year like the hand of a dial.

The Pleiades tells you **when**. The Bear tells you **where**. And neither set of people chose: an object that disappears becomes a calendar, an object that never disappears becomes a compass, and no culture in nineteen investigations ever overrode it.

And a gift

Ursa Major also handed over something the whole project had been missing without knowing it: **an example of the real thing.**

There is a genuinely ancient, genuinely inherited star myth attached to these stars. It is called the **Cosmic Hunt**: hunters pursue a large animal, the animal is wounded, and they all become the constellation. The folklorist Yuri Berezkin has mapped it, and the claim made for it is exactly the claim made for the Pleiades sisters, that it is Palaeolithic and crossed the Bering land bridge.

And here is the thing. **The two do not look remotely alike.**

The Cosmic Hunt has a **bounded distribution**: northern and central Eurasia and the Americas, apparently absent elsewhere, with edges you can draw on a map. It has **gaps inside its own range** that have been mapped, places like the stretch from Alaska to Labrador where Ursa Major is well known but is not connected to the hunt at all, which is exactly what inheritance with loss looks like. It has **systematic variation**, with elk in one half of its range and bear in the other. Somebody has computed a **phylogeny** for it. And it has a **relative in sub-Saharan Africa** that landed on a different constellation entirely.

The Pleiades sisters have none of that. Three disconnected patches, no patterned variation, locally contradictory solutions each fitted neatly to its own society's law, and no phylogeny.

That is not proof. It is something better than proof for an ordinary reader: **we now know what support would have looked like, and the sisters do not have it.**

Eleven: The story travels, the number does not

And then the Belt itself, tested properly rather than assumed, and it gave the finding that ties the whole thing together.

Berezkin reports that across sub-Saharan Africa the Cosmic Hunt is the only widespread star myth, and that there it is always attached not to Ursa Major but to **Orion**.

You can see it from the other side in the names. The Tswana have three dogs chasing three pigs: Orion's Sword pursuing Orion's Belt. The /Xam have the tortoises carried on a stick. The !Kung have three zebras, which are game. Olcott recorded three old men pursued and three widows following.

So the same structure is in both places.

On Ursa Major the hunt has seven members, because there are seven stars. On Orion's Belt it has three, because there are three. On the Magellanic Clouds, in New South Wales, a pursuit story has two women, because there are two patches. And on the Pleiades it has seven, which is more than the eye delivers, and only there does somebody have to go missing.

Nobody carried a number from Siberia to the Kalahari. What travelled, or was reinvented, was a **shape of relationship**: some beings pursuing some other beings, and ending up in the sky. Every single sky filled in its own arithmetic from what was actually overhead.

The story supplies the grammar. The object supplies the number. And the wound appears only where the two disagree.

Twelve: A woman's left foot

Then the Hyades, which is the Pleiades' own neighbour. Same constellation, same season, fourteen degrees away, rising within the hour. Plural, compact, uncountable: all three of the Pleiades' original properties.

One difference. **Aldebaran.** Magnitude 0.9, blazing orange, sitting right in the middle of it, putting out roughly thirty times the light of anything else in the figure. (It is not even a member of the cluster. It is a foreground star less than half as far away, lying in the same direction by accident. No naked eye has ever known that.)

If the original account were right, the Hyades should still be a heap.

It is never a heap. And what it is instead is the same in six unrelated traditions, and it is not what I predicted.

Mesopotamia called it **is-lê**, the jaw of the bull, and the crown of the sky god Anu. Greece read it as the **face** of Taurus. Rome called it the little sows, by mistranslating the Greek. Arabia called it **al-Qilās**, the little she-camels, **driven along in front of** the great camel, which is Aldebaran. India called it **Rohiṇī śakaṭa**, the cart **pulled by** Rohiṇī, which is Aldebaran. China called it **Bì**, the Net: a rabbit-net with a long handle, with Aldebaran counted **inside** it as one of its eight stars.

Look at the grammar. The cluster is never the subject of its own name. It is what the bull chews with, what the god wears, what Rohiṇī pulls, what the camel drives, what the net catches.

A bright star does not organise the faint ones around it. It absorbs them. The group stops being a group and becomes a single thing, and the bright star is its owner or its anatomy.

Ooldea

And then the best evidence in either book, and it comes from the Great Victoria Desert.

Daisy Bates spent years at Ooldea recording the language and traditions of the local people. In a Kokatha account, re-analysed in our own century by Leaman and Hamacher, the vain hunter **Nyeeruna**, who is Orion, desires the **Yugarilya** sisters, who are the Pleiades. Standing between them is **Kambugudha**, who blocks him and humiliates him.

Kambugudha is the Hyades. And **Aldebaran is her left foot**.

Hold the two clusters side by side in that one story.

The Pleiades is a **group of sisters**. Plural, named plural, acting plural. The Hyades is **one woman**. A single person, with the bright star as part of her body.

Same teller. Same sky. Same night. Same story, with both objects inside it, interacting. No Greeks, no Ptolemy, no possible route of transmission for either reading. And the two clusters are fourteen degrees apart and differ in exactly one respect.

Everything I had spent two books trying to separate, what the sky does from what culture does, the Kokatha separated in a single story, and the separation falls precisely where the photometry says it should.

(The same tradition, incidentally, appears to encode the variability of the red stars, and gets the relative speeds right: Nyeeruna's fire-magic is Betelgeuse and Kambugudha cannot raise hers in time, and Betelgeuse does vary both more and faster than Aldebaran.)

And Greece wrote both answers down

One more thing from the Hyades, and it may be the sharpest single fact in the whole investigation.

The same Greek mythographers, in the same century, in the same genre, with the same sky, produced **three separate explanations** for a missing Pleiad.

On the Hyades, fourteen degrees away, those same authors could not agree whether there were five, six or seven, listed different names in different books, and **never once asked where the missing ones were.**

Why? Because the Pleiades tradition had committed to **seven**, from a number system rather than from looking, and seven was not deliverable. The Hyades tradition never committed to anything. There was no fixed number to fail.

The wound is downstream of the number. It was never downstream of the sky.

Thirteen: The fog that forecasts

Praesepe next, the faint cluster in the middle of Cancer, which tested something new: an object that is **not plural at all**.

It contains more than a thousand stars. To an unaided eye it is a single grey smudge. Galileo pointed the first telescope at it in 1609 and resolved forty.

Before that, for two thousand years, it was a **container** or a **mist** and nothing else. The Greeks called it *Phátnē*, the crib. The Romans called it *Praesepe*, the manger, with two flanking stars as the donkeys that feed from it. The Arabs called it *al-Ma'laf*, the stall. Aratos called it the little mist. Hipparchus called it the little cloud. Pliny called it the foggy star in the breast of Cancer.

And nobody ever gave it a number. Not once, in a thousand years of continuous observation by the best-equipped naked-eye astronomers in the world, looking at an unavoidable object in the zodiac.

Stop on that, because it settles an argument that both sides of the Pleiades debate have been having without evidence. The whole question turns on whether ancient eyes under dark skies resolved more than modern eyes do. Praesepe is the test neither side ran, and the record is unanimous. They looked straight at it, for a millennium, and reported a fog.

Then Galileo counted forty, and within a few generations the English-speaking world was calling it **the Beehive**: the same container, now explicitly full of a swarm.

A name changed within a century of the eye changing, in a literate culture with a two-thousand-year written attachment to the old word, and nobody fought it.

Names are not memory. Names are the current report.

The barometer

And Praesepe gave something lovely.

Aratos, around 270 BCE, and Pliny three centuries later, both recorded that when the sky is otherwise clear but Praesepe cannot be seen, a storm is coming. The practice survived into medieval weather lore.

And it works. High thin cirrus, the first visible sign of an approaching front, is nearly transparent to bright point sources and noticeably opaque to a faint, spread-out one. A first-magnitude star shines straight through it. A magnitude 3.7 smudge does not. So a sky that still shows all its usual stars while Praesepe has vanished is a sky with high cloud in it, which is a sky with weather coming.

They had a naked-eye cirrus detector. They read it correctly. They had no idea why it worked.

And here is the thing that made me sit back. In the Andes, communities judge the **brightness of the Pleiades** in June to forecast the rains, and the practice was verified in *Nature* in 2000: it works because El Niño years bring high cirrus that dims the cluster, months before the drought arrives.

Two civilisations that never met. Two faint clusters. The same method: **watch whether the fuzzy thing is still there.** Both physically valid. One forecasts tomorrow, the other forecasts next season.

The property that defeats counting is the property that measures the air.

Fourteen: Two patches in the south

By this point the account looked solid, and that is exactly when you should distrust yourself.

Because look where the evidence came from. Mesopotamia, Greece, Rome, Arabia, India, China, Christian Europe. Literate astronomies in contact for two thousand years, several of them demonstrably reading each other's books, and most of the rest filtered through nineteenth-century collectors who had been taught Latin at school.

A fair sceptic could say: this is not a finding about human beings. It is a finding about **one enormous interconnected library** and the people who transcribed everything else into its categories.

The Magellanic Clouds answer that, and they are the only thing that can.

They sit below declination minus sixty-nine. **Invisible from every single place the rest of the evidence came from.** Ptolemy never catalogued them and could not have. Neither could Hipparchus, al-Ṣūfī, Hesiod, the Book of Songs or the Rigveda. The first European to write them down was a sailor.

So: what do people who have actually lived under them call them?

The Kamilaroi and Euahlayi have them as two **buralga**, brolgas, and in Parker's account a mother and daughter who were pursued, caught by the whirlwind spirit, turned into birds and placed in the sky when they died. Howitt recorded that the dead go to a dark patch within them called *Maianba*, endless water. The Adelaide people called them *Ngakallamurro*, paroquet-ashes, the white ash of roasted lorikeets. In Western Australia they are the campfire of an old couple too frail to get their own food. Māori names include *Te Reporepo*, the swamp. Portuguese and Dutch sailors called them the Cape Clouds for two centuries before Magellan's name stuck.

Ash. Fire. Water. Smoke. Swamp. Cloud. **Substances.** And **no gathering-name anywhere**, on two objects that between them contain something like thirty billion stars, because not one of those stars resolves.

And the most specific prediction in the sealed file held: **the pair is named far more often than either member.** A mother and a daughter. An old couple. Two birds chased together, caught together, transformed together. Nobody names one of them alone.

Which gave a finding I had not predicted at all. Across the ladder, a faint group with a bright neighbour gets **absorbed** into it, or **annexed** by it, or **furnished** as the thing between two of them. The Clouds have no bright neighbour at all, so they took hold of **each other**.

A faint thing is never named by itself. It is named by what it is with.

And the Kamilaroi story is the Pleiades motif, element for element: women, pursued, transformed, placed in the sky. With **two** of them, because there are two patches. And nobody missing, and no explanation needed, because the arithmetic closes.

Fifteen: A frond and a lock of hair

The last object was Coma Berenices, the faintest and most scattered thing in the study, and it broke the one property left untested: **compactness**.

A dozen faint stars fanning out across five degrees of empty spring sky, with nothing in the whole constellation brighter than magnitude 4.26.

In Alexandria in 241 BCE, Queen Berenice vowed her hair for her husband's safe return from a war, cut it, and dedicated it in a temple. It vanished overnight. Konon, the court astronomer, told her it had been taken into the sky, and pointed at some faint stars near the lion's tail. It is the only constellation in this entire story whose origin has a name, a date, a place and a motive.

The Arabs, working from Ptolemy, called it the tuft, the braid, the tail-tuft.

And Babylon, long before and quite independently, called it *Sissinnu*: the frond, or spadix, of a date palm, held by the goddess Erua and paired with the neighbouring Furrow the way dates were paired with barley.

A palm spadix and a lock of hair have nothing in common as objects. One is agricultural, one is cosmetic. One belongs to a harvest goddess, one to a particular murdered queen.

But they are the same perception, exactly. Many fine things, attached loosely at one end, spreading outward, none of them individually the point, and no boundary where they stop.

Each culture reached into its own life for the nearest object of that shape. Babylonia, which ate dates, found a frond. Alexandria, which had a political problem involving a haircut, found hair.

The vocabulary is local. The perception is not.

And Coma gave one more thing, by being the only object in either book with **no function at all**. No calendar, no rite, no weather sign, nothing, from anybody, in four thousand years of being looked at and named by Babylon, Greece, Arabia and China. Because it is too faint and too diffuse to deliver an event, and an object that cannot anchor a date gets no festival, no proverb, and no story that needed it.

Function first. Then story. And where there is no possible function, there is almost nothing at all.

Sixteen: 1949

Six objects. Six removals. One result in each case.

Remove **countability** and you get a count. Remove **leaderlessness** and the group stops existing and becomes somebody's jaw or cart or foot. Remove **plurality** and you get a container or a substance. Remove **compactness** and you get a frond or a braid. Remove compactness and countability together and you get a wagon, a plough, a bear.

All four properties are necessary. The Pleiades is the only object in the near sky that holds all four, and it is the only object that gets called a crowd.

That was the answer, and it was a good answer, and I thought it was the last one.

Then I went looking for whether the threshold I had been describing in the sky shows up anywhere else, and found that it had been measured seventy-five years ago, in a laboratory, by people who have never once pointed their work at a star.

It is called **subitizing**. The word was coined in 1949.

Subitizing is the fast, accurate, effortless perception of how many things are in a small set, **without counting**. It is not quick counting. It is a different operation, using different attention, and you can see the join in the reaction times: inside the range each extra item costs almost nothing, and past it the cost jumps and the errors arrive.

And the range is about four.

Not four as a figure of speech. Four as a measured, replicated boundary. When experimenters removed the possibility of scanning, by presenting the dots as afterimages so the eye could not move across them, longer viewing and helpful arrangements **failed to raise the limit at all**. Enumeration stayed effectively perfect up to four and collapsed to errors of twenty to thirty per cent beyond it. The limit barely shifts across a lifetime: about three for a seven-year-old, four for an adult.

Now put that against the whole investigation.

Orion's Belt is three. Inside the range. That is why nobody on Earth ever had to count it, and why eight unrelated peoples on four continents arrived at the number instantly and correctly and none of them ever lost one.

The Magellanic Clouds are two. Inside the range. Six peoples, named as a pair.

Ursa Major is seven, spread over twenty-five degrees. Outside the range, but far enough apart that the eye can walk them one at a time. Serial counting works. Seven sages, seven oxen, seven gods, nothing missing.

And the Pleiades is six or seven packed inside two degrees. Too many to take in at a glance. Too close together to count one by one.

It falls into the single gap in human enumeration where **neither system can reach it.**

That is nineteen investigations and four hundred and fifty-three sources, and it is a number, and the number is four.

And it is not about eyes

The part that changes everything: **the limit of about four is not visual.**

It has been found in **touch**, when people report how many fingertips were stimulated, replicated many times, and found in adults blind from birth who have never seen anything at all. It has been found in the counting of **sounds** presented one after another. The same elbow in the data, at the same place, in senses that share no organ. A lioness who hears three unknown calls will leave; with four of her sisters beside her, they will go and look.

So the threshold does not belong to the eye. The eye only decides whether light arrives as separate points or as texture. The boundary is further in, at **whatever in a mind holds separate things as separate**, and it is the same size in every sense it has been measured in, and it is older than our species.

Which means the thing all human beings share here is not a story, and not a sky, and not even a kind of eye.

Fourteen peoples did not report what they saw. They reported where their attention gave out.

Seventeen: What this is for

There is one more turn, and it is the reason any of this matters to somebody who is never going to read a lunar-mansion table.

Go back and read the Pleiades names one more time. A heap. A herd. A crowd. An assembly. A crowded bunch. Gathered together.

Every single one is a mass noun. Not seven stars. An *amount* of stars.

Now listen to what every contemplative tradition on Earth reports at depth, in whatever vocabulary it happens to have.

Not thoughts: **thinking**. Not breaths: **breathing**. Not sensations: **sensation**. Not moments: **time**.

That is the identical event. Count nouns becoming mass nouns. The plural dissolving into a substance. **A heap is not a lot of things. A heap is what things become when you stop being able to hold them apart.**

Which explains something I had wondered about for years without expecting an answer.

Why does every tradition on Earth tell you to **count your breaths**, and why does the counting always stop?

Count to ten and begin again. Count to five. Count the out-breath only.

Now we know. Counting past four requires serial, effortful attention, which is a different machine from the effortless one, and occupying that machine with something harmless is the entire point of the instruction. And then, at some point, the count goes. You were at six, and then you are simply breathing, and time has passed.

That is not the practice failing. **That is the practice arriving.** You crossed the line. The breaths stopped being items and became breathing, which is the mass noun, which is the heap.

Which is *Subaru*. Gathered together.

Every tradition that ever told a person to count their breaths built a machine for walking them to the edge of enumeration and letting them step off it. They just did not know it was four.

And the words those traditions use for the state they are after are all the same family: gathered, collected, settled, recollected, one-pointed, together. **They are heap-names, for a person.** The same word fourteen peoples reached for when they looked at the one object in the sky that defeats counting.

Not because anyone remembered anything. Because it is the same threshold, approached from two directions, and a language only has one word for it.

Eighteen: What they all saw

So here is the whole thing, as short as it will go.

The sisters are not humanity's oldest story. Thompson's sentence holds for two peoples in twelve. Four traditions make them men. Mesopotamia wrote for two thousand years and never lost one. The calendar is the constant, thirteen out of thirteen, and the function is older than the tale everywhere the layers can be dated.

Nobody got the seven by counting. It was brought, every time, from a number system or a sacred number or the Great Bear or, in our case, from Greece. And wherever a people brought a number the sky could not deliver, something had to be missing, and a story got built to explain the absence, and the story was always local, always beautiful, and always false.

Underneath all of it is a layer older than any story: a description, carried by children learning to talk, in fourteen traditions and nine language families, saying the same thing in different words. **Many of something. Together. In one place.**

And underneath *that*, which is where this ended up, is not the sky at all.

It is an edge about four things wide, sitting in every human being who has ever lived, in sight and in touch and in hearing, present in people who have never seen. On one side of it things stay themselves and cost you nothing. On the other side they stop being separate and become an amount.

Everything in this story happened at that edge. The sky just happens to contain **one object sitting exactly on it**, visible to everybody, unchanged for the whole of human history, which is why fourteen peoples who never met all walked outside, looked up, and made the same sound.

The peoples in this book found that edge by going out at night and looking at the only thing in the world that sits on it.

The traditions that teach sitting still found the same edge by counting to four.

They were never doing different things.

> ✦ **If you want to try it.** Go outside on a clear winter night and let your eyes have ten minutes without a screen. Find Orion's Belt. Notice how fast the number arrives. Three, immediately, before you decide to count. That is below the line, and it costs you nothing. Now move up and to the right, past the orange star, to the small misty knot.

Stay with it. Notice the number trying to form and failing. Five, then six, then something at the edge of your eye that might be seven, and gone when you look straight at it.

That flicker is the whole of this book, and you just ran the experiment in under a minute with your own eyes.

Then, whenever you like, close them. Breathe gently, in through the nose, out a little longer. Count four breaths, and on the fifth let the counting go. Notice that nothing is missing. Not at three, not at the many, not at one. Nothing is missing because you never decided in advance how many there should be.

Breathe gently, and never force or hold the breath.

A note on the evidence, and on how this was made

This is the narrative version of three scholarly volumes, and everything asserted here is graded and sourced in them.

The Seven Who Are Six: The Pleiades in Thirteen Breaths walks thirteen peoples in thirteen breaths each, with 363 sources. *The Leadered and the Scattered: Five Controls for the Gathering Hypothesis* walks the six control objects, with 81 further sources and the sealed pre-registration printed in full. *The Edge of Counting* takes what the two make together and reads it through the lens of *Breath Awakens*.

Those volumes use the house method: two hands, one holding what has been measured and one holding what it means, with every claim graded established, supported, contested, open, beyond test or symbolic. This narrative drops the grading so it can be read, which means a reader who wants to know how firm any particular sentence is should go to the volume it came from. The contemplative material in Chapter Seventeen is offered as meaning, not as a claim about the world.

The limits are real and are stated at length in those books. No primary language was read: no Akkadian, Greek, Latin, Arabic, Sanskrit, Classical Chinese, Setswana, Jul'hoan, Te Reo or Western Desert language. Berezkin was read in English. Two of the six control objects rest on only two independent traditions each. Several European and Asian star names descend from compilations of 1899 and 1911 that are unreliable outside Europe. Much of the non-European material here comes through nineteenth-century collectors, and where modern peer-reviewed re-analyses exist they are what the volumes cite. Several of these traditions are living, and some contain restricted knowledge; nothing beyond what their own keepers have published is recorded anywhere in this work.

One error was found during the work and left in the record rather than removed, and one result went against the prediction and is printed as a counter-case. Both are in the second volume.

The labour was done by an AI working under the author's method and grading, reading fast and holding a great deal at once, with no idea what any of it meant until the shape appeared. It is a mirror, not a mind. The central finding of the first book was picked out of a buried line by a third voice in the room, and the attribution is not a courtesy.

A mirror can find a threshold. It cannot cross one. Everything in the last chapter describes something that happens in a body over a few quiet minutes, written by something that has neither. Whether any of it is true is a question for the person who goes and sits down.

In Harmony, Small Things Grow Towards Unity.
